Therefore, each angle of the square is an inscribed angle in the circle that intercepts the circle at the endpoints of the diameters. A dilation by a scale factor of 4 centered at the origin preserves parallelism and \((0, -2) \rightarrow (0, -8)\).

The line \(3y = -2x + 8\) does not pass through the center of dilation, so the dilated line will be distinct from \(3y = -2x + 8\). Since a dilation preserves parallelism, the line \(3y = -2x + 8\) and its image \(2x + 3y = 5\) are parallel, with slopes of \(-\frac{2}{3}\).

Since a dilation preserves parallelism, the line \(4y = 3x + 7\) and its image \(3x - 4y = 9\) are parallel, with slopes of \(\frac{3}{4}\).

The slope of \(-3x + 4y = 8\) is \(\frac{3}{4}\).

The given line \(h\), \(2x + y = 1\), does not pass through the center of dilation, the origin, because the \(y\)-intercept is at \((0, 1)\). The slope of the dilated line, \(m\), will remain the same as the slope of line \(h\), -2. All points on line \(h\), such as \((0, 1)\), the \(y\)-intercept, are dilated by a scale factor of 4; therefore, the \(y\)-intercept of the dilated line is \((0, 4)\) because the center of dilation is the origin, resulting in the dilated line represented by the equation \(y = -2x + 4\).

The line \(y = 2x - 4\) does not pass through the center of dilation, so the dilated line will be distinct from \(y = 2x - 4\). Since a dilation preserves parallelism, the line \(y = 2x - 4\) and its image will be parallel, with slopes of 2. To obtain the \(y\)-intercept of the dilated line, the scale factor of the dilation, \(\frac{3}{2}\), can be applied to the \(y\)-intercept, \((0, -4)\). Therefore, \(\left(0, \frac{3}{2}, -4 \cdot \frac{3}{2}\right) \rightarrow (0, -6)\). So the equation of the dilated line is \(y = 2x - 6\).

The line \(y = 3x - 1\) passes through the center of dilation, so the dilated line is not distinct.
The line $y = -3x + 6$ passes through the center of dilation, so the dilated line is not distinct.

The line $y = \frac{3}{2}x - 4$ does not pass through the center of dilation, so the dilated line will be distinct from $y = \frac{3}{2}x - 4$. Since a dilation preserves parallelism, the line $y = \frac{3}{2}x - 4$ and its image will be parallel, with slopes of $\frac{3}{2}$. To obtain the $y$-intercept of the dilated line, the scale factor of the dilation, $\frac{3}{4}$, can be applied to the $y$-intercept, $(0, -4)$. Therefore, \( \left(0 \cdot \frac{3}{4}, -4 \cdot \frac{3}{4}\right) \rightarrow (0, -3) \). So the equation of the dilated line is $y = \frac{3}{2}x - 3$.

$3 \times 6 = 18$

\[ \sqrt{(32 - 8)^2 + (28 - -4)^2} = \sqrt{576 + 1024} = \sqrt{1600} = 40 \]

The line is on the center of dilation, so the line does not change. $p: 3x + 4y = 20$

\[ \sqrt{(2.5 - 1)^2 + (-.5 - 1.5)^2} = \sqrt{2.25 + 4} = 2.5 \]
ANS:
No, the line $4x + 3y = 24$ passes through the center of dilation, so the dilated line is not distinct.

Triangle \( X'Y'Z' \) is the image of \( \triangle XYZ \) after a rotation about point \( Z \) such that \( ZX \) coincides with \( ZU \). Since rotations preserve angle measure, \( \overline{ZY} \) coincides with \( 
\overline{ZV} \), and corresponding angles \( X \) and \( Y \), after the rotation, remain congruent, so \( \overline{XY} \parallel \overline{UV} \). Then, dilate \( \triangle X'Y'Z' \) by a scale factor of \( \frac{ZU}{ZX} \) with its center at point \( Z \). Since dilations preserve parallelism, \( \overline{XY} \) maps onto \( \overline{UV} \). Therefore, \( \triangle XYZ \sim \triangle UVZ \).

Translations preserve distance. If point $D$ is mapped onto point $A$, point $F$ would map onto point $C$. $	riangle DEF \cong \triangle ABC$ as $AC \cong DF$ and points are collinear on line $l$ and a reflection preserves distance.

ANS:

Yes. The sequence of transformations consists of a reflection and a translation, which are isometries which preserve distance and congruency.

No. Since $BC = 5$ and $ST = \sqrt{18}$ are not congruent, the two triangles are not congruent. Since rigid motions preserve distance, there is no rigid motion that maps $\triangle ABC$ onto $\triangle RST$.

It is given that point $D$ is the image of point $A$ after a reflection in line $CH$. It is given that $\overleftrightarrow{CH}$ is the perpendicular bisector of $BCE$ at point $C$. Since a bisector divides a segment into two congruent segments at its midpoint, $BC \cong EC$. Point $E$ is the image of point $B$ after a reflection over the line $CH$, since points $B$ and $E$ are equidistant from point $C$ and it is given that $CH$ is perpendicular to $BE$. Point $C$ is on $CH$, and therefore, point $C$ maps to itself after the reflection over $CH$. Since all three vertices of triangle $ABC$ map to all three vertices of triangle $DEC$ under the same line reflection, then $\triangle ABC \cong \triangle DEC$ because a line reflection is a rigid motion and triangles are congruent when one can be mapped onto the other using a sequence of rigid motions.

Reflections are rigid motions that preserve distance.

$\overleftrightarrow{LA} \cong \overleftrightarrow{DN}$, $\overleftrightarrow{CA} \cong \overleftrightarrow{CN}$, and $\angle DAC \perp \angle LCN$ (Given). $\angle LCA$ and $\angle DCN$ are right angles (Definition of perpendicular lines). $\triangle LAC$ and $\triangle DNC$ are right triangles (Definition of a right triangle). $\triangle LAC \cong \triangle DNC$ (HL). $\triangle LAC$ will map onto $\triangle DNC$ after rotating $\triangle LAC$ counterclockwise $90^\circ$ about point $C$ such that point $L$ maps onto point $D$.

Yes. The triangles are congruent because of SSS $\left(5^2 + 12^2 = 13^2\right)$. All congruent triangles are similar.
\[ \Delta XYZ, \overline{XY} \cong \overline{ZY}, \text{ and } \overline{YW} \text{ bisects } \angle XYZ \text{ (Given). } \Delta XYZ \text{ is isosceles (Definition of isosceles triangle). } \overline{YW} \text{ is an altitude of } \Delta XYZ \text{ (The angle bisector of the vertex of an isosceles triangle is also the altitude of that triangle). } \overline{YW} \perp \overline{XZ} \text{ (Definition of altitude). } \angle YWZ \text{ is a right angle (Definition of perpendicular lines).} \]

As the sum of the measures of the angles of a triangle is 180°, \( m\angle ABC + m\angle BCA + m\angle CAB = 180° \). Each interior angle of the triangle and its exterior angle form a linear pair. Linear pairs are supplementary, so \( m\angle ABC + m\angle FBC = 180°, m\angle BCA + m\angle DCA = 180°, \text{ and } m\angle CAB + m\angle EAB = 180° \). By addition, the sum of these linear pairs is 540°. When the angle measures of the triangle are subtracted from this sum, the result is 360°, the sum of the exterior angles of the triangle.
